ECMI Modelling Week, 21 July 2018

# Problem statement

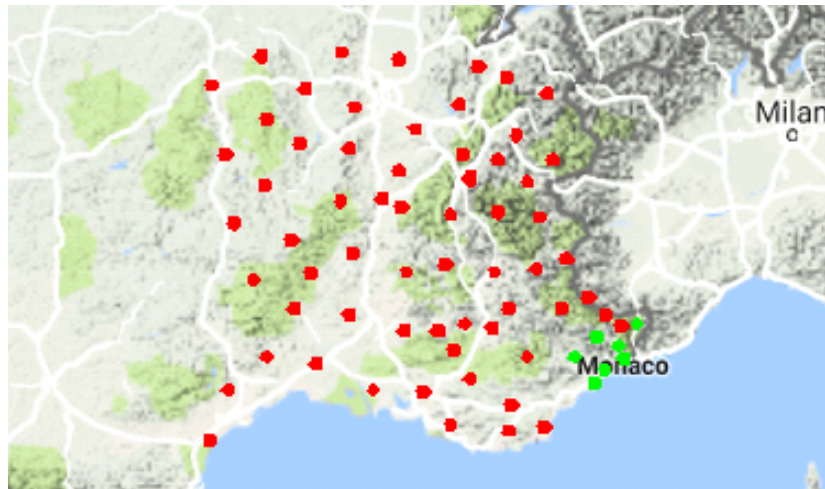

- ▶ Seismic monitoring is used to study the behaviour and composition of the underground floor
- ▶ There is a time drift in the monitors' clocks, causing inaccuracies in analysis
- ▶ Continuous synchronization to the Global Positioning System for accurate timing is not possible
- ▶ A reliable method to correct the time drift of the clocks' is required

# The network of seismic monitors

- ▶ The network consists of 73 seismic monitors
- ▶ For initial analysis, 7 stations are selected

# The network of seismic monitors

# Numbers of working stations and connections to stations during one year

- ▶ The maximum of simultaneously working stations is 52 out of 73
- ▶ The maximum of connections is 1326
- ▶ If two monitors are working simultaneously, they are connected

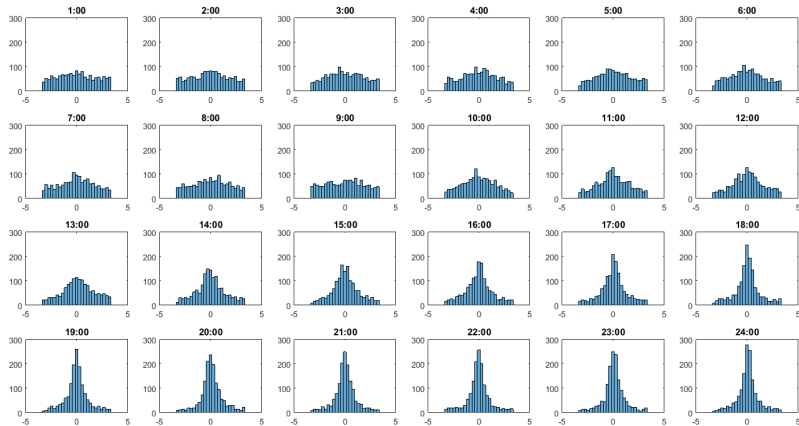

# Time-delay signal characteristics

- ▶ Data recorded in one second intervals
- ▶ Time-delay cross-correlation is computed in one-hour intervals
- ▶ Each connection is computed only once
- ▶ Tracing time-delays recorded by one station over a year

# Histograms showing time delays recorded by all active stations over 24 hours

# Comparison of time delay of the furthest and the closest station pairs

- Time delays are smaller between stations which are close to each other

# Graph approach to model the data

- ▶ Measured time delays  $\hat{\delta}$  between stations:

$$\hat{\delta} = \delta(t) + \varepsilon(t) \quad (1)$$

- ▶ Graphs  $\mathcal{G}_{\delta} = (\mathcal{V}, \mathcal{E}, \hat{\delta})$ ,  $\mathcal{G}_r = (\mathcal{V}, \mathcal{E}, \mathbf{W})$

- ▶ Metric:

$$f_i(\hat{\delta}) = K_i \quad (2)$$

with

$$f_i(\hat{\delta}) = \sum_j \delta_{ij} \quad \text{and} \quad K_i = f_i(\mathbf{W}) = \sum_j w_{ij} \quad (3)$$

text here

# Signal denoising and extracting clock drift

- ▶ We specify a cost function  $c(\hat{\delta})$  measuring the deviation of the metric:

$$c(\hat{\delta}) = \sum_i e_i^2(\hat{\delta}) = \sum_i (f_i(\hat{\delta}) - K_i)^2 \quad (4)$$

- ▶ Error is minimized with gradient descent updates on  $\hat{\delta}$ :

$$\hat{\delta}^{(t+1)} = \hat{\delta}^t - \mu \sum_i e_i(\hat{\delta}^t) \frac{df_i(\hat{\delta}^t)}{d\hat{\delta}^t} \quad (5)$$

- ▶ The noise  $\varepsilon_{ij}$  between each pair of two stations is caused by clock drifts  $\Delta_i$  and  $\Delta_j$ , and other errors  $e_{ij}$ :

$$\varepsilon_{ij} = \Delta_i - \Delta_j + e_{ij} \quad (6)$$

## Solving individual clock drifts (1/2)

- We have overdetermined inverse problem of the form

$$\mathbf{G}\mathbf{s} = \mathbf{m} \quad (7)$$

$$\begin{bmatrix} 1 & -1 & 0 & 0 & \dots & 0 \\ 1 & 0 & -1 & 0 & \dots & 0 \\ 1 & 0 & 0 & -1 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & 0 & 0 & 0 & \dots & -1 \\ 0 & 1 & -1 & 0 & \dots & 0 \\ 0 & 1 & 0 & -1 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 1 & 0 & 0 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & \dots & 0 & 1 & -1 \end{bmatrix} \begin{bmatrix} \Delta_1 \\ \Delta_2 \\ \Delta_3 \\ \Delta_4 \\ \vdots \\ \Delta_k \\ \vdots \\ \Delta_{n-1} \\ \Delta_n \end{bmatrix} = \begin{bmatrix} \Delta_1 - \Delta_2 \\ \Delta_1 - \Delta_3 \\ \Delta_1 - \Delta_4 \\ \vdots \\ \Delta_1 - \Delta_n \\ \Delta_2 - \Delta_3 \\ \Delta_2 - \Delta_4 \\ \vdots \\ \Delta_2 - \Delta_k \\ \vdots \\ \Delta_{n-1} - \Delta_n \end{bmatrix} = \begin{bmatrix} \Delta_{12} \\ \Delta_{13} \\ \Delta_{14} \\ \vdots \\ \Delta_{1n} \\ \Delta_{23} \\ \Delta_{24} \\ \vdots \\ \Delta_{2k} \\ \vdots \\ \Delta_{(n-1)n} \end{bmatrix}$$

- Matrix  $\mathbf{G}$ 's rank is  $n - 1$

## Solving individual clock drifts (2/2)

- ▶ Ordinary least squares regression

$$\|\mathbf{G}\mathbf{s} - \mathbf{m}\|_2^2. \quad (8)$$

- ▶ Tikhonov regularization is employed

$$\|\mathbf{G}\mathbf{s} - \mathbf{m}\|_2^2 + \|\mathbf{\Gamma}\mathbf{s}\|_2^2, \quad (9)$$

for some suitable Tikhonov matrix  $\mathbf{\Gamma} = \alpha \mathbf{I}$

- ▶ The explicit solution is hence given by

$$\hat{\mathbf{s}} = (\mathbf{G}^T \mathbf{G} + \mathbf{\Gamma}^T \mathbf{\Gamma})^{-1} \mathbf{G}^T \mathbf{m}. \quad (10)$$

# Results

# Conclusion

- ▶ A graph method to recover clock drift in large time-delay network was developed
- ▶ Clock drifts for the three most influential monitors and five others close by were computed
- ▶ Clock drift may account for up to 1 % inaccuracy in timing at each time point
- ▶ The drift varies over time

## **Future work:**

- ▶ A synthetic dataset to verify the effectiveness of the method
- ▶ Analyze the complete network of monitors
- ▶ Develop and test other metrics
- ▶ Carry out sensitivity analysis
